Islands of the Bird Cult

The picturesque site of Orongo was chosen because of its position opposite the islands Motu-nui, Motu-iti, and Motu-kaukau. Two of the islets are almost inaccessible, and it is possible to land on Motu-nui only when the sea is calm. Hundreds of thousands of birds make temporary abode on these solitary rocks, some of them coming for the winter and others for the summer. (See list of birds, p. 18.) The *manu-tara* (sooty tern), whose eggs were the principal objects of the *tangata-manu* feast, arrive from August to October. When I visited the island in November, it was covered with birds nesting on rocks and in the high grasses. Frightened by our arrival, they took flight, swirling around our heads in dense clouds. The natives who had accompanied us gathered in one hour more than a hundred eggs which they ate on the spot.

On Motu-nui there are several caves which were occupied by the *hopu* (servants) while they awaited the coming of the *manu-tara* and while they searched for the first eggs.

On the wall of the largest of these caves, which is about 6.5 meters long by 4 meters wide and 2 meters high, there is an incised image of an *ao* (dance paddle) which is 2.4 meters long. With Dr. Lavachery, I discovered another image which figures a *ri-miro* (breastplate) ending in two cocks' heads.

Besides this large cave, the entrance of which is visible, there are other smaller caves with narrow mouths. On the walls of one cave were some incised figures, among them that of a bird now in the Trocadero Museum. From the mouth of the bird protrudes a flame-like design, composed of many lines. This appears to be a conventional representation of the deafening cries of the birds. Another drawing, also taken from this cave and preserved in the Museum du Cinquantenaire at Brussels, shows a man with long ears.

The most spectacular of these caves is entered by a narrow passage descending at a sharp angle. Routledge (194, p. 275) saw five skeletons there, but I noticed only two; they were untouched and lying on a bed of boulders. Over them hung a big red head, carved in the hard mud of the ceiling, more than 500 mm. long and crossed in the lower part by horizontal lines. It resembled the god with big eyes figured in many petroglyphs on the island. Two small heads were seen in the same cave. A double-headed bird, carved in relief, had been partially destroyed by natives or by visitors hunting for curios. Fortunately another bird in the same cave was reproduced by Routledge (194, pl. 17). Neither Routledge nor anyone in our party was able to get information about the unusual presence of skeletons in this cave, which was probably not intended for a burial vault. The ornaments which covered its walls preclude such a possibility. These carvings are coated with red ochre and stand out from a white background which seemed to me to be natural, although Routledge believed it had been painted.

Another of the caves on the islet was believed by Routledge (194, p. 275) to have been transformed into a sepulchre, but the bones must have been thrown out, since I found none there. A statue presented to the British Museum by Routledge is said to have been removed from one of these caves and to have been called Titahanga-o-te-henua. It is purported to have marked the boundary between Tuu and Hotu-iti.

Mataveri

The third place closely associated with the ceremonies of the bird cult was Mataveri on the northern slope of Rano-kao, where now stands the house
